Agentic AI applied to cybersecurity

I developed it myself, in my current role, with the objective of making the migration and maintenance of detection rules between SIEMs fast, consistent and measurable.

The problem

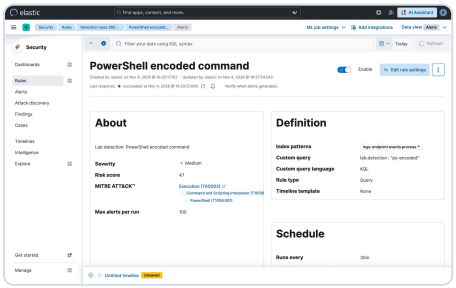

Migrating and maintaining thousands of detection rules between SIEM platforms by hand is slow, inconsistent and leaves dead rules that never fire.

What I built, in my current role

Python pipelines based on AI agents that migrated more than 2,000 detection rules between SIEM platforms. Each rule goes through automatic quality control, metadata enrichment and mapping to MITRE ATT&CK, with an automatic assessment of coverage and obsolescence; rules that do not meet the standard are quarantined instead of being migrated as they are.

Quality is guaranteed by an automated test battery (via MCP) and metadata-driven coverage tracking against MITRE ATT&CK and ATLAS. For investigations and query validation I use Elastic's native MCP plus a proprietary Python MCP with reusable skills that migrate and author detections under strict standards.

I also contributed to an AI tool that finds MITRE ATT&CK and ATLAS coverage gaps and generates and tests UEBA detection rules, and I build assistants connected to Splunk, Elastic and Jira through the Model Context Protocol (MCP). The goal is always the same: agents that make detection engineering faster and more reliable, with a person reviewing what matters.

An Elastic rule with its MITRE ATT&CK mapping, in my lab
