Multi-site Splunk reference architecture

I designed and published it myself, with the objective of showing how to build a Splunk platform that survives the loss of a data center.

In detail

A published reference design for a multi-site Splunk Enterprise platform with high availability and disaster recovery, drawn to Splunk Validated Architecture patterns: data sources and collection tier, indexer cluster across two sites with replication and search factors, multi-site search head cluster, dedicated Enterprise Security cluster, cluster manager redundancy, SmartStore on object storage with cross-region replication, management plane, backups and a drilled failover runbook. Sizes are representative.

The two-site platform case study on this site shows the same approach applied to a representative client, with synthetic figures and a real method.
